

# Comparison of the two heat map processes when change map is ticked

Marion Louveau

2018-01-25

stack 2 active with parents label ticked

Trial with the classical heat map process: decreasing chosen because stack 2 is active

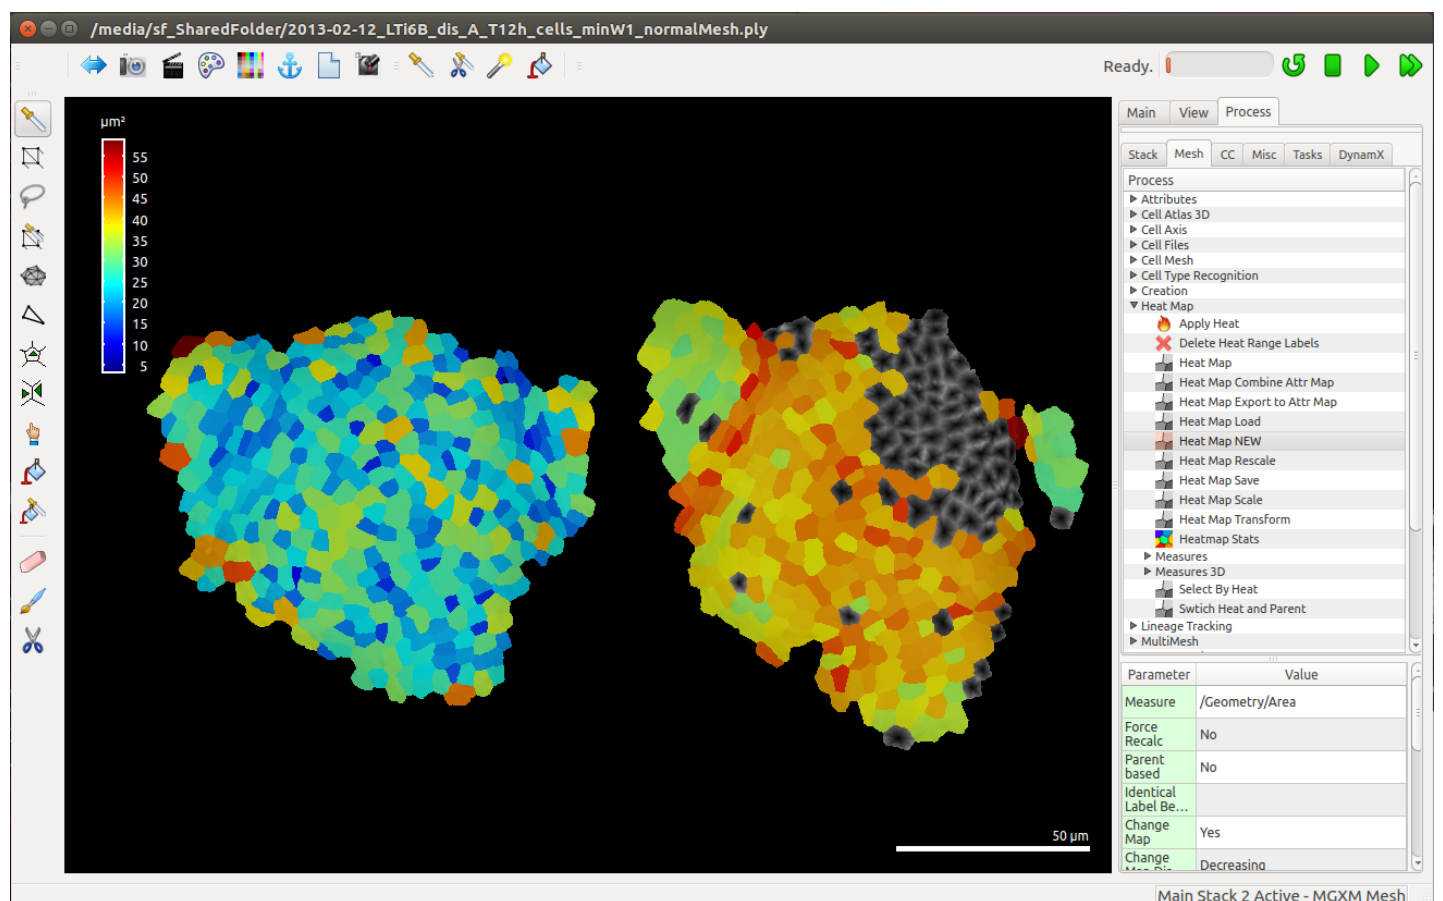

I get an heatmap on Stack 2 active. Growth is important in the organs and low in the boundaries between organs and meristem, as expected.

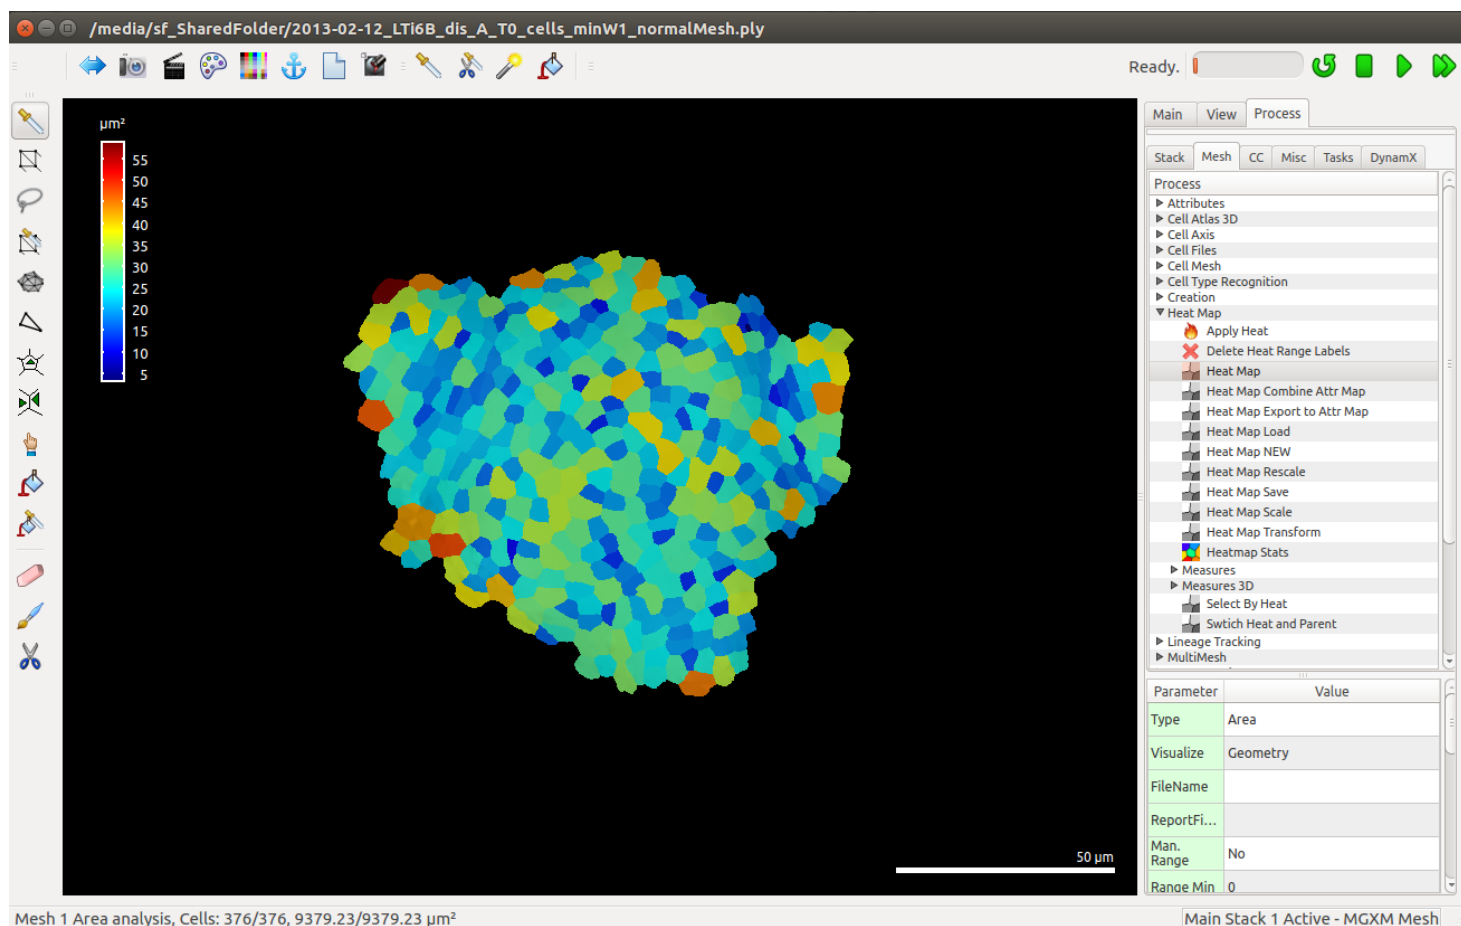

Again, I choose stack as active

Now I try with the new heat map process. I tick the same parameters. Stack 2 is active with parent label and stack 1 inactive with labels. The default growth time is different from the classical heat map process but it is not affecting the calculation of the ratio I think.

I get a heat map on both meshes. None of the two correspond to the heat map I obtained previously.

Here is how the Heat Map area looks like for the first timepoint (in Stack1)
